1.1 Why do we need iFAS?

Nowadays, multiple image processing areas have shown the necessity of what is called *fidelity assessment*, i.e., objective assessment of differences between a reference and a test image sample [19, 20, 23]. More specifically, the objective of fidelity assessment is to determine if there are visual differences between a given test sample and the corresponding reference with respect to certain features and if so to quantify those differences [24, 25]. For instance, in the research of color science and imaging technology images are assessed according to the exhibited color differences [19]. This includes image processing tasks such as color correction [14, 16], color quantization [10], color mapping [18], among others. In medical applications, image fidelity is often based on quantifying the visibility between a structure of interest such a vessel and its surrounding anatomical background [20, 21]. In such a case, the feature of interest is image contrast and thus the image with the highest fidelity is the one with the lowest contrast difference relative to the reference [20]. In the textile industry, the evaluation is based on the lifetime and appearance retention which is closely related to the surface appearance of the textile material. For example, appearance retention of textile floor coverings is based on measuring fine changes of global texture between the reference (new carpet) and test sample (“used” carpet) [9]. Therefore, the task of fidelity assessment is to measure visual differences between the two images of the textile material under inspection considering texture as the feature of interest [23].

The variety of image domains requiring image fidelity assessment implies the need for application-specific or even application-tailored methodology rather than a one-size-fits-all solution. While many candidate algorithms already exist, testing them and identifying the best ones for a given use case is far from an easy exercise. Thus, it often takes a lot of time and effort to even prepare the test environment for benchmarking, validation and/or developing.

1.2 What is iFAS?

The image Fidelity Assessment Software (iFAS) is a software tool designed to assist researchers, engineers and other users in the process of image fidelity assessment. iFAS provides easy access to a range of state-of-the-art methods as well as intuitive visualizations that aid data analysis. The software is freely available to all for non-commercial use. iFAS includes a range of common mechanisms for image fidelity assessment including computation of fidelity measures on a single pair of images and/or in a full database, visualization of pixel-wise image differences and histogram of the image differences, scatter plots and correlation analysis between human scores and objective measures. Furthermore, iFAS is designed with the purpose of making the interface user friendly even for adding new functionality (by modifying or extending the source code). This user interface takes away the interaction of the user with the code, reducing the time spent on the fidelity assessment phase of a merging technology and/or benchmarking of image processing algorithms.

1.3 System requirements

The minimum system requirements to run iFAS are:

- 1000 MHz processor
- 2048 MB RAM
- 400 MB of hard-drive space (or USB stick)
- 3D Acceleration Capable Video card with at least 512 MB

The recommended operating system is GNU Linux Ubuntu 14 or higher [8]. iFAS is developed using Python 2.7 [1]; GTK+ [2]; Scipy 0.17.0 together with its core packages, particularly, NumPy 1.11.0, Matplotlib 1.5.1, pandas 0.17.1, nose 1.3.7, Cython 0.25.1 and Scikits 0.12.3 [7]; PIL 1.1.7 [5]; PyGObject (aka PyGI) 3.20.0 [3]; Pycairo 1.10.0 [4]; PyWavelets 0.5.0 [6]. Therefore, those packages need to be pre-installed before running iFAS. In Ubuntu Linux, the following commands install the required packages (please look at your system configuration):

```
$ sudo apt-get install python-numpy python-scipy python-matplotlib python-pandas  
$ sudo apt-get install ipython ipython-notebook python-sympy python-nose  
$ sudo apt-get install build-essential  
$ sudo pip install -U scikit-image
```

Furthermore, iFAS has a set of extra Python packages with specific tools designed for image fidelity assessment, e.g., color difference measures, image contrast measures, texture analysis algorithms, among others (See Section 2.4 for the complete list of available functions).

1.4 Running iFAS

To run iFAS first make sure that your system has the minimum requirements described in the previous Section. In Ubuntu Linux,

```
$ cd /folder/to/files/iFAS/
```

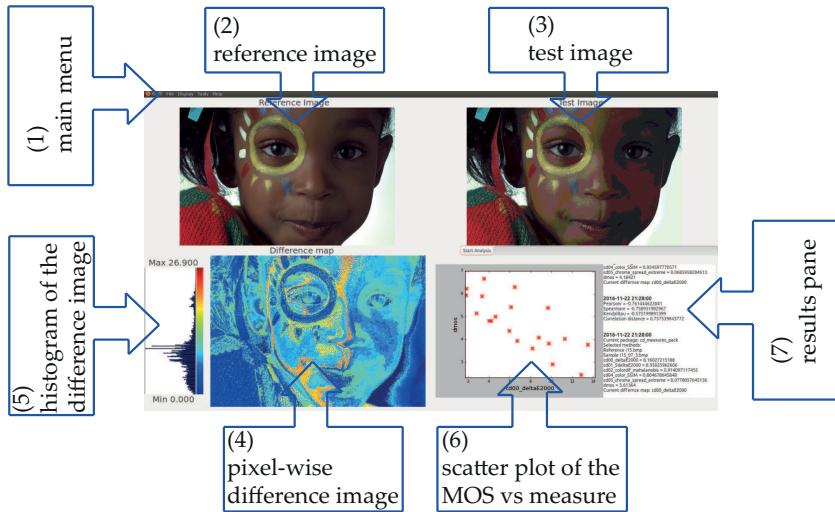

Figure 1.1: iFAS main window screenshot.

```
$ python2.7 iFAS.py
```

Afterwards iFAS user interface is open. Figure 1.1 shows a screenshot of iFAS user interface with each of its components. The interface displays seven main components: (1) the main menu, (2) the reference image, (3) the test image, (4) the pixel-wise difference image, (5) the histogram of the pixel-wise difference image, (6) the scatter plot of the MOS versus the measure values for a given reference, and (7) the results pane.

The reference image is the reference image selected by the user. The test image is the test image selected after selecting the reference image. The scatter plot of MOS versus the measure values is the space designed for plotting the values of the selected fidelity measures against subjective scores or other fidelity measure values from the current package. In the results pane, the current values of the current session are displayed. The pixel-wise difference image displays the pixel-wise difference of the fidelity measure selected by the user between the reference and test images. The histogram of the pixel-wise difference image is a 255 bins histogram of the pixel-wise difference image is displayed. In Chapter 2, we describe how to change each of these components and we show in deep their functionality. Note that this guide only pretends to introduce iFAS functionality and not interpret that data because that is up to the user and its own application. In Chapter 3, we study some case scenarios where an interpretation of the data is given based on the application at hand.

Chapter 2

iFAS Functionality

In this chapter we explore every functionality available on iFAS. To do so, we use examples step by step showing screenshots of each major step.

2.1 Single Source - Single Sample

This type of analysis only computes the selected fidelity measures between one reference image and one corresponding test image, i.e., the current images displayed on the user interface (images are selected using a file chooser). This analysis is executed as follows on the main menu: File ⇒ New ⇒ Single Source ⇒ Single Sample. After clicking a pop up window with the list of available Python packages is displayed (see Figure 2.1(a)). Here, one and only one package can be selected. By selecting the package a similar pop up window appears displaying the available functions in the package (see Figure 2.1(b)). Here, the user can select one or multiple functions (hold ctrl key + left mouse click) to be computed in the pair of images to be selected. The images are selected right after selecting the methods. The file chooser appears twice, one for the reference and one for the test image (see Figure 2.1(c) and 2.1(d)), respectively. iFAS accept the most common types of image files: BMP, JPEG, JPEG 2000, PNG, PPM, TIFF, XPM [5]. Afterwards, the software starts processing the selected images using the selected methods. The status bar shows the status of the processes on the current pair of images (note that the computational time of these processes depend of the system capabilities). When the processes have finished, the software displays in the results pane the results of the selected methods and a message identifying that the processes have finished (see Figure 2.2). Additionally, the pixel-wise difference image and its histogram are updated. These are the details displayed on the results pane:

```
2016-12-05 21:22:39
Current package: cd_measures_pack
Reference i03.bmp
Sample i03_07_2.bmp
cd00_deltaE2000 = 6.22467
cd01_SdeltaE2000 = 6.20208
cd02_colordif_mahalanobis = 0.65185
cd03_colorfulness_diff_Gao = 0.01154
cd04_color_SSIM = 0.84766
cd06_colorhist_diff = 0.68961
cd07_weighted_deltaE = 2.20900
Current differnce map: cd00_deltaE2000
2016-12-05 21:22:39
Process Finished!
```

This is the most basic type of analysis on iFAS used mainly for the development of new fidelity measures because it is possible to display different statistics of the same method as well as the pixel-wise difference

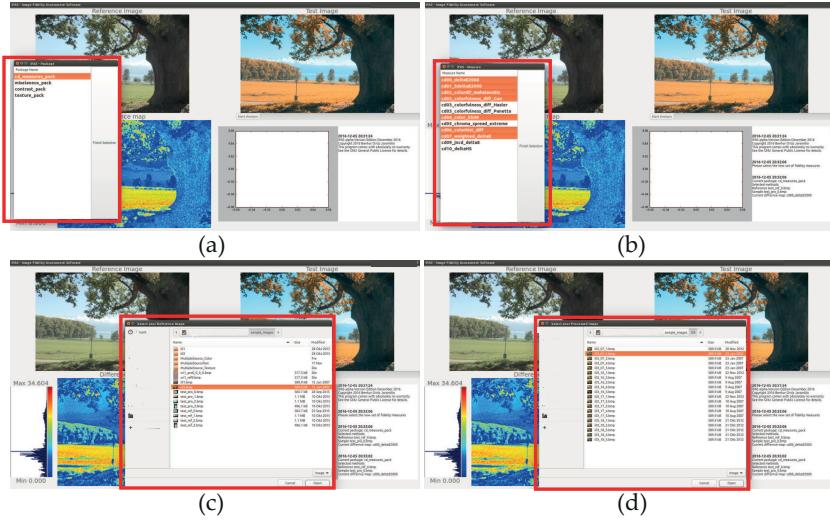

Figure 2.1: All the pop up windows displayed on the Single Source \Rightarrow Single Sample analysis and Single Source \Rightarrow Multiple Sample analysis. (a) list of available Python packages, (b) the available functions in the package, (c) the reference and (d) the test image file chooser.

and the error distribution (the histogram of the pixel-wise image difference). The different statistics can be compared by setting different function names per computed value (see Section 3.1 to see an example). It can be used with other purposes if the source code is modified. This only includes to modify your own code (see Section 2.4 for an example of how to perform this operation).

2.2 Single Source - Multiple Sample

This type of analysis computes the fidelity measures selected by the user between one reference image and a number of corresponding test images as specified by the user using a file chooser. The process is very similar to the one explained on Section 2.1, therefore we use the same Figures. This analysis is executed as follows: File \Rightarrow New \Rightarrow Single Source \Rightarrow Multiple Sample. After clicking a pop up window with the list of available Python packages is displayed (see Figure 2.1(a)). Here, one and only one package can be selected. By selecting the package a similar pop up window appears displaying the available functions in the package (see Figure 2.1(b)). Here, the user can select one or multiple functions to be computed in the set of images to be selected. The images are selected right after selecting the methods. The file chooser appears twice, one for the reference and one for the test images (see Figure 2.1(c) and 2.1(d)), respectively. Note that the second file chooser allows now multiple file selection (hold ctrl key + left mouse click). This means that the user can select as many image files as desires. Afterwards, the software starts processing the selected images using the selected methods. The status bar shows the status of the current pair of images (note that the computational time of these processes depend of the system capabilities).

Here we are going to show a couple of options that are very useful for a set of images (reference image plus a number test images). We use as case scenario, a reference with a set of 20 processed images and 5 different color difference measures. In this case, when the process has finished, the software displays the last processed images on the user interface and print the data for all the values. We only display the results for two of the image examples:

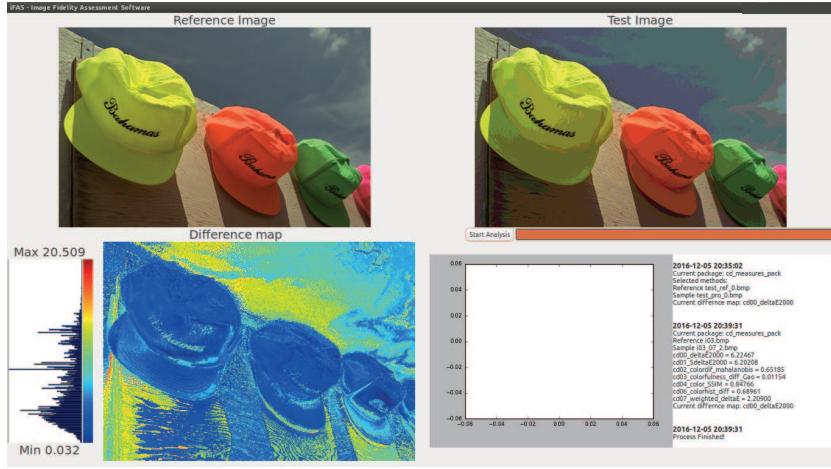

Figure 2.2: Result of the Single Source \Rightarrow Single Sample analysis.

```

2016-12-05 22:14:18
Current package: cd_measures_pack
Reference i01.bmp
Sample i01_18_4.bmp
cd00_deltaE2000 = 11.66716
cd01_SdeltaE2000 = 11.75023
cd02_colordif_mahalanobis = 4.28796
cd04_color_SSIM = 1.71947
cd05_chroma_spread_extreme = 0.21545
Current differnce map: cd00_deltaE2000

```

Additionally, the pixel-wise difference image and its histogram are updated.

```

2016-12-05 22:14:23
Current package: cd_measures_pack
Sample i01_18_5.bmp
cd00_deltaE2000 = 18.43680
cd01_SdeltaE2000 = 18.08736
cd02_colordif_mahalanobis = 12.94531
cd04_color_SSIM = 1.76997
cd05_chroma_spread_extreme = 0.31109
Current differnce map: cd00_deltaE2000
Process Finished!

```

2.2.1 The scatter plot space

In the scatter plot space is possible to plot all the computed values between two selected methods and/or subjective scores if available and add it by the user (see Section 2.2.4). The scatter plot can be modified as follows Display \Rightarrow Plots \Rightarrow Mx Vs My. Afterwards two pop up windows (one after the other) with the list of measures (see Figure 2.1(b)) are displayed for selecting the x-axis and y-axis, respectively. Figure 2.3(a) shows the results after executing such a process. The scatter plot shows the with x-markers each point of the computed data for detecting any relationship between the data for the current reference content at hand. iFAS computes and displays on the results pane the following correlation indexes typically used as performance indicators of fidelity measures: Pearson Coefficient of Correlation (PCC) [11], Spearman Rank Order Coefficient of Correlation (SROCC), [12], Kendall Rank Coefficient of Correlation (KRCC) [13] and Coefficient of Correlation of Distances (CCD) [26]. Note that these indexes are computed with the values currently displayed on the scatter plot component.

2016-12-05 22:52:05
 Current x axis: cd00_deltaE2000
 2016-12-05 22:52:05
 Current y axis: cd05_chroma_spread_extreme
 2016-12-05 22:52:05

Pearsonr = 0.72673
 Spearmanr = 0.64060
 Kendalltau = 0.47368
 Correlation distance = 0.66875

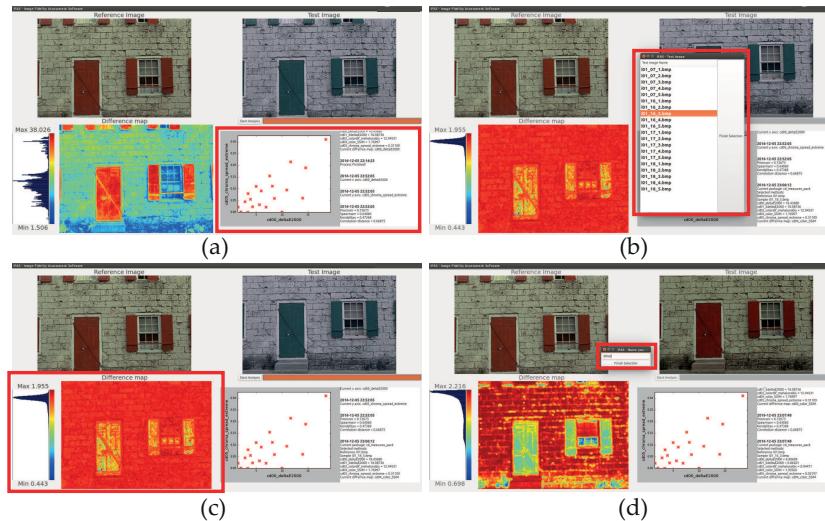

Figure 2.3: Result of the Single Source \Rightarrow Multiple Sample analysis. (a) scatter plot for the selected methods, (b) reference and test samples, (c) the image difference and (d) naming the new measure values or subjective scores from file.

2.2.2 Saving and loading analysis

After computing a set of complex algorithms over a number of images it comes handy to be able to store such data for further analysis. On iFAS current analysis can be stored by using the option File \Rightarrow Save. The software stores automatically the necessary variables to continue the session another time. iFAS requests the file name and stores it with file extension .iFAS to be recognized as the results from an iFAS analysis. To continue a previous session it is necessary to go to the option File \Rightarrow Load. The software retrieves automatically the necessary variables to continue the session from an .iFAS file using a file chooser.

2.2.3 Changing the reference, test and difference image

The reference (when there is multiple sources available, see Section 2.3) and test images are changed using Display \Rightarrow Test image. Two consecutive pop up windows appear with the list of available reference and test images (see Figure 2.3(b)), respectively. Note that the image difference also changes in this case but not the used measure to compute the pixel differences. To change the measure used to compute the image difference is necessary to go to Display \Rightarrow Image difference. Thereafter, the current image difference can be selected from the displayed list of available fidelity measures (see Figure 2.3(c)).

2.2.4 The MOS scores and other pre-computed methods file

iFAS provides an option to add pre-computed measure values or subjective scores such as MOS or DMOS. This is very useful when there is already pre-computed data from other experiments and/or adding the subjective scores from the database at hand. This can be performed using the option Tools ⇒ Add ⇒ Add MOS or pre-computed measure from file. Afterwards a file chooser appears for the selection of a text file with the values. Note that the user has the responsibility to make sure that the test image corresponds in scene to the reference images and the corresponding values. The text file should be formatted as follows: name reference image, space, name test image, space, the measure value (file_name_reference file_name_test value). Every line corresponds to a one and only one test image. For example:

```
ref3.bmp test0.bmp 24.0000000000  
ref3.bmp test1.bmp 87.2857142900
```

After selecting the file an input window appears asking for the name of the new added data. The name should be typed by the user and it can be any character combination (see Figure 2.3(d)). However, there is a reserved name by the software which is dmos. dmos name is very important because iFAS uses this variable for many benchmarking analysis using subjective scores (see Section 2.3 for details about this processes). Therefore, the subjective scores in iFAS are recognized with the variable name dmos.

2.3 Multiple Source - Multiple Sample

This type of analysis computes the fidelity measures selected by the user between a number of reference images and a number of test images. This is like executing a Single Source ⇒ Multiple Sample several times using different reference images and their corresponding test samples. Note that, the user has the responsibility to make sure that the test image corresponds in scene to the reference images. This is achieved by preparing a text file with the names of the images with the following format: each line of the text file (named with extension .iFASproj to be recognized from the other files, see Figure 2.4(a)) represents one reference image and each test image is separated by spaces:

```
file_name_reference file_name_test0 file_name_test1 ... file_name_testn
```

Every line corresponds to a one and only one reference image and its corresponding test images. For example:

```
ref0.bmp ref0_test0.bmp ref0_test1.bmp ref0_test1.bmp ref0_test2.bmp ref0_test3.bmp  
ref1.bmp ref1_test0.bmp ref1_test1.bmp ref1_test1.bmp ref1_test2.bmp ref1_test3.bmp  
ref2.bmp ref2_test0.bmp ref2_test1.bmp ref2_test1.bmp ref2_test2.bmp ref2_test3.bmp
```

This is an example for 3 references each one with 4 test samples.

Caution: the test images need to correspond in scene to the reference images in the text file.

After selecting the file the software performs the operation for every single combination between each reference and its corresponding test images. Note that the computational time of these processes depend of the system capabilities. After finishing the software displays the computed values in the results pane. Afterwards a range of analysis can be performed with this data. We will describe these analysis in the following paragraphs. To illustrate this type of analysis, we use as example a set of 4 reference images, 20 sample images and 5 different color difference measures.

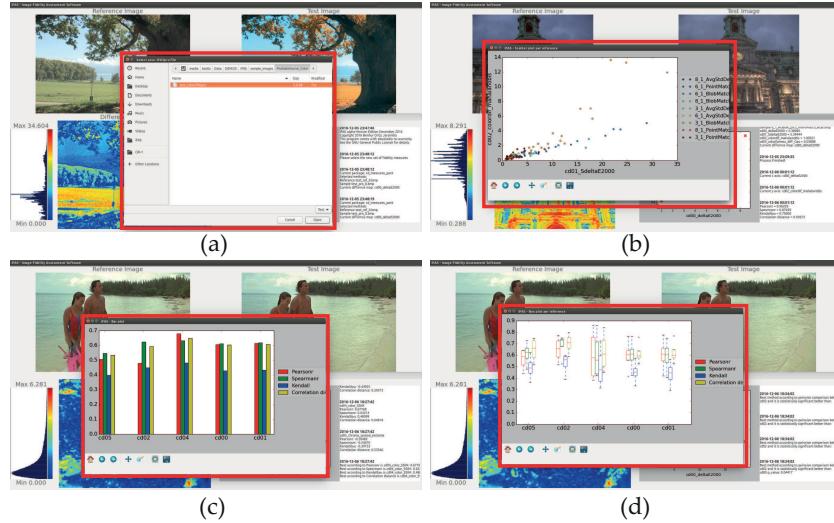

Figure 2.4: Result of the Multiple Source - Multiple Sample analysis. (a) list of images file selection, (b) scatter plot between fidelity measures for all references, (c) bar plot of the correlation values and (d) box plot of the correlation values per reference.

2.3.1 All data scatter plot

The all data scatter plot is a scatter plot of two selected measures or one measure and subjective scores for all reference samples. In this scatter plot each reference sample is labeled with a different marker color. This option is located on Display \Rightarrow Plots \Rightarrow Mx Vs My all data. Two consecutive pop up windows appear with the list of methods to be plotted. Figure 2.4(b) shows the pop up window with the resulting scatter plot. Note that this figure can be stored in vector format (.eps, .svg) and/or any other image format such as (.jpg, .png, .tif). In Chapter 3 all images are stored in vector format with the purpose of showing the capabilities of iFAS to produce scientific publications type images. For the rest of this Chapter we show only screenshots with the purpose of showing iFAS user interface.

2.3.2 Global correlation analysis

If the user has provided a subjective scores file and it was named dmos (see Section 2.2.4), it is possible to perform a global correlation analysis. The global correlation analysis is located on Tools \Rightarrow Correlation analysis \Rightarrow Global correlation bar plot. Afterwards a pop up window appears with the bar plot of the correlation values between the fidelity measures and the subjective score (dmos). Figure 2.4(c) shows a screenshot of the resulting window. Additionally, the correlation values are printed in the result pane as well as the best performing fidelity measures according to these correlation values. Here, we only show for one of the fidelity measures and for the best performing one.

2016-12-06 18:27:42	2016-12-06 18:27:42
cd05_chroma_spread_extreme	Best according to Pearsonr is cd04_color_SSIM: 0.67768
Pearsonr: -0.50489	Best according to Spearmanr is cd04_color_SSIM: 0.63213
Spearmanr: -0.54670	Best according to Kendall is cd04_color_SSIM: 0.48098
Kendalltau: -0.39733	Best according to Corr dist is cd04_color_SSIM: 0.48098
Correlation distance: 0.53346	

2.3.3 Correlation per reference and pairwise comparisons

A box plot analysis is very useful for identifying how well the measures perform if the content remains the same (reference image). In iFAS this analysis is performed with Tools \Rightarrow Correlation analysis \Rightarrow Correlation per source box plot. Figure 2.4(d) shows the resulting box plot. The correlation values are computed between the fidelity measures and the subjective scores (dmos). The software provides on the results pane a pairwise comparison between the measures with the purpose of identifying if there are statistically significant differences in terms of the performance between them (cf. Garcia et. al. [15] and Section 2.4 for details about pairwise comparisons). Here, we show only the example for CCD:

2016-12-06 18:34:02	cd01
p_values - Correlation distance	1.000 1.629 0.655 0.264 0.655
cd05	0.371 1.000 0.180 0.044 0.180
cd02	1.345 1.820 1.000 0.502 1.000
cd04	1.736 1.956 1.498 1.000 1.498
cd00	1.345 1.820 1.000 0.502 1.000

Table 2.1: p-values of the pairwise comparison corresponding to the example in Section 2.3.3

	cd05	cd02	cd04	cd00	cd01
cd05	1.000	1.629	0.655	0.264	0.655
cd02	0.371	1.000	0.180	0.044	0.180
cd04	1.345	1.820	1.000	0.502	1.000
cd00	1.736	1.956	1.498	1.000	1.498
cd01	1.345	1.820	1.000	0.502	1.000

This print out corresponds to Table 2.1. This table is interpreted as follows: the i th measure is statistically significant better in terms of correlation than the j th measure if the p-value of the i th row and j th column is lower than the significance level, e.g., 0.05 (see Section 2.4 for more information about pairwise comparisons). Therefore, considering previous values, iFAS returns the following analysis:

2016-12-06 18:34:02

Best method according to pairwise comparison between Correlation distance

cd02 and it is statistically significant better than:

cd00 p_value: 0.04417

This means that cd02 is the best performing measure but its performance is only statistical significant better than cd00.

2.3.4 Non-linear regression

In fidelity assessment is very important to build a model after selecting the appropriated set of measures and test it on unseen data. iFAS simulates such a process by building models using samples provided by the user divided into training and test subsets. The regression analysis is located at Tools \Rightarrow Regression analysis \Rightarrow {Linear, Quadratic, Cubic, Exponential, Logistic, Complementary error}. That is, it is possible to fit the data into the six most common mapping functions:

- linear function $y = mx + b$,
- quadratic function $y = ax^2 + bx + c$,

- cubic function $y = ax^3 + bx^2 + cx + d$,
- exponential function $a + \exp(bx + c)$,
- logistic function $a/[1 + \exp(-bx - c)]$ and
- complementary error function $0.5 - 0.5 \operatorname{erf}[(x - a)/(\sqrt{2}b)]$ [22].

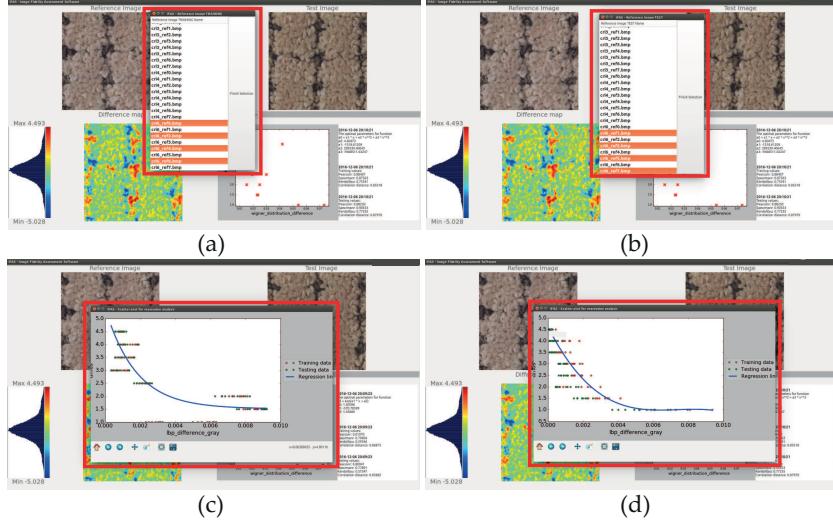

Figure 2.5: Result of the Regression analysis. (a) selection of the training samples, (b) selection of the training samples, (c) screenshot of a logistic model and (d) screenshot of a cubic model.

Lets assume we have a set of images composed of scanned printed images from the CRI standard photo set (see Section 3.2 for details about this example). That is a total of 512 test and 32 reference samples. We use the well known Local Binary Patterns (LBP) algorithm [17] to compute the texture features from the images. After selecting the desired type of function, iFAS asks the user to select the set of training and test samples (Figures 2.5(a) and 2.5(b), respectively). This is performed by using two consecutive pop up windows. Here the user can select as many training and test samples as desired. We show on Figures 2.5(c) and 2.5(d) the regression analysis for two references from the example in Section 3.2. The dots are the actual data and the line shows the fitted model using the training data. The parameters of the model are shown in the result pane together with the correlation coefficients for the model. This information comes handy for estimating the performance of the model for external use of the built models. We show as example the information displayed on the result pane for the model on Figure 2.5(d):

```

2016-12-06 20:10:21
The optimal parameters for function
a0 + a1 * x + a2 * x**2 + a3 * x**3
a0: 4.60473
a1: -1518.61209
a2: 209530.40643
a3: -9468511.63247
2016-12-06 20:10:21
Training values:
Pearsonr: 0.88407
Spearmanr: 0.87563
Kendalltau: 0.75341
Correlation distance: 0.85518
Testing values:
Pearsonr: 0.88250
Spearmanr: 0.90553
Kendalltau: 0.77235
Correlation distance: 0.87970
  
```

2.4 Adding new iFAS packages

TODO: To include the description of the available measures, packages and modules.

Chapter 3

Quick examples to use iFAS

In this Chapter we describe and explore use case scenarios with the purpose of showing the advanced functionality of iFAS for the analysis of objective fidelity measures. The use cases are the modeling of texture differences on a textile floor covering database, the evaluation of 3 color correction algorithms for a merging a multiview imaging technology using 2 image color difference measures and the design of a fidelity measure. The set of methods used for the analysis in this Chapter were selected from [19, 22, 23].

3.1 Designing a global contrast measure for images

TODO:

3.2 Textile floor covering assessment using non-linear regression

TODO:

3.3 Improving a multiview imaging system
